

## Lecture 23

Review  $B$  a block with  $p$ -core  $b = (b_1, b_2, \dots, b_r)$  and weight  $w$ .

Put  $B$  on an abacus with  $r+pw$  beads. Let  $\Gamma_i$  be the # of beads on runner  $i$ .

Suppose  $\Gamma_i = \Gamma_{i-1} + k$ ,  $k \geq w$ , for some  $i \geq 2$ .

Let  $\bar{B}$  be block of  $\Sigma_{n-k}$  having  $p$ -core obtained from swapping runners  $i-1, i$  on abacus of  $b$ .

Thm  $B$  and  $\bar{B}$  are Morita Equivalent.

Notation  $\bar{b}$  is  $p$ -core corr. to  $\bar{B}$

$e = e_B$  central idempotent corr to  $B$

$\bar{e} = e_{\bar{B}}$  central idempotent corr to  $\bar{B}$ .

### Restriction/Induction

Recall In char 0,  $\text{Res}_{\Sigma_{n-1}} S^\lambda \cong \bigoplus_{\text{remov nodes } A} S^{\lambda^A}$

$\text{Ind}_{\Sigma_{n-1}} S^\lambda = \bigoplus_{\text{add node nodes } B} S^{\lambda^B}$

Thm In char  $p$ ,  $\text{Res}_{\Sigma_{n-1}} S^\lambda$  has a filtration with factors  $\cong$  to the various  $S^{\lambda^A}$ . Similarly for  $\text{Ind } S^\lambda$ .

Suppose  $H < G$ ,  $b$  a block of  $kH$ ,  $U$  a  $kG$ -module.

$\text{Res}_b U$  denotes the summand of  $U$  in block  $b$

Similarly  $\text{Ind}_H^B V$  denotes summand in block  $B$

Moreover, given a block  $B$  and a  $B$  module  $U$ ,  $U$  is naturally a  $kG$ -module by letting other blocks act as 0.

Example  $p=3$   $w=2$   $b=(4,2)$

$\bar{b} = \frac{xxx}{x} = (1,3,1)$

Prop Swapping columns  $i-1, i$  of a basis gives a bijection between partitions  $\lambda \in B$  and  $\bar{\lambda} \in \bar{B}$ .

Proof The map  $\lambda \rightarrow \bar{\lambda}$  is clearly 1-1. But 2 blocks of weight  $w$  have same # of  $\mathbb{Z}$  simples, so onto.

$\lambda = \frac{\begin{matrix} x & x & x & x \\ x & x & x & x \\ x & x & x & \\ x & & & \end{matrix}}{x} = (4,4,3,1)$        $\bar{\lambda} = \frac{\begin{matrix} x & x & x & x \\ x & x & x & x \\ x & x & & \end{matrix}}{x} = (4,4,2)$

## Branching Behavior

Let  $S^\lambda \in B$ . Let  $\lambda^{(1)}, \dots, \lambda^{(k)}$  be column weights in  $\lambda$ , so  $w = \sum d_i i!$

Lemma If abacus for  $\lambda$  has bead in spot  $(j, i-1)$  then also in  $(j, i)!$

pf Define  $v$  by  $\lambda^{(i-1)} = w - v$  so  $\lambda^{(i)} \leq v$ .

Beads in col  $i-1$  lie in rows  $1 \rightarrow \Pi_{i-1} + w - v$

But  $\lambda^{(i)} \leq v$  means 1<sup>st</sup>  $\Pi_i - v$  rows of col  $i$  are filled

$$\Pi_i - v = \Pi_{i-1} + k - v \geq \Pi_{i-1} + w - v \quad //$$

Lemma Let  $S^\lambda \in B$ . Then

$$S^\lambda \downarrow_B \sim k! S^\tau$$

$$S^\tau \uparrow_B \sim k! S^\lambda$$

Proof We are removing  $k$  nodes, net effect has to be to shift  $k$  beads runner  $i$  to  $i-1$ , there are  $k!$  ways. //

Recall  $S^\lambda \approx D^\lambda + D^{\mu}$   $\mu$  smaller.  
if prec

Thm Let  $D^\lambda \in B$  (so  $\lambda$  is prec)

$$1. D^\lambda \downarrow_B \sim k! D^\tau \quad 2. D^\tau \uparrow_B \sim k! D^\lambda$$

3.  $B$  and  $\bar{B}$  have same dec. matrix

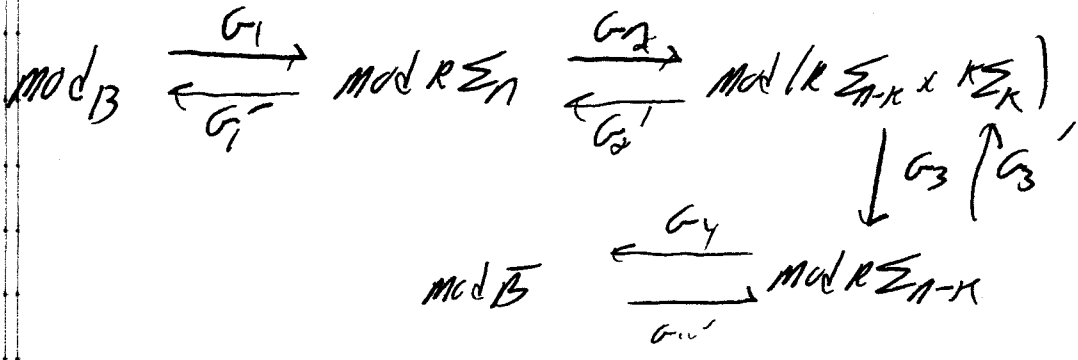

4. Same Cartan matrix

Proof Choose  $\lambda_1 > \lambda_2 > \dots > \lambda_4$  prog in  $B$ .  $\bar{\lambda}_1 > \bar{\lambda}_2 > \dots > \bar{\lambda}_4$  in  $\bar{B}$ .  
True for  $D^{\lambda_1}$ . Now induct. //

Prop  $S^{\lambda} \cdot \bar{e} \cong S^{\bar{\lambda}} \otimes_F R \Sigma_K$  as a  $\Sigma_{n-k} \times \Sigma_K$  module.  
 $D^{\lambda} \cdot \bar{e} \cong D^{\bar{\lambda}} \otimes_F R \Sigma_K$  " "

PF Look at actual bases.

The Morita Equivalence

- $G_1, G_1', G_4, G_4'$  as discussed early.
- $G_2, G_2'$  restriction and induction.

For  $G_3$   $\Sigma_{n-k} \times \Sigma_K$  modules =  $\Sigma_K^{\text{op}} - \Sigma_{n-k}$  bimodule

$$G_3(M) = R \otimes_{R \Sigma_K^{\text{op}}} M \quad \text{right } R \Sigma_{n-k} \text{ module}$$

$$G_3'(N) = \text{Hom}_K (R_{\Sigma_K} \otimes N_{\Sigma_{n-k}})$$
